Creating a bibliography with package `biblatex` and a given `.bbl` file and without an additional `biber` run.

Herbert Voß

January 9, 2022

1 Introduction

Often publishers do want to use a bibliography created by biber. The problem is that they often do not trust external programs which they do not use. By default `biblatex` cannot simply read the by biber created `.bbl` file.

This package modifies the macro for reading the file, so that publishers need only the package `biblatex` and `biblatex-readbbl`. An existing `.bbl` file can be insert into the main dococument and then created on-the-fly by the filecontents environment (look into the documents source for an example).

This package uses by default the macro `\jobname` as main file name for the bibliography (.bbl file). You can read another file by passing the file name via the optional argument:

```
\usepackage[colorlinks]{hyperref}
\usepackage[style=authoryear,maxbibnames=99]{biblatex}
\usepackage[bblfile=demo]{biblatex-readbbl}
```

In this case the file `demo.bbl` is used.

2 Example

The example is created without an additional biber run.
